# **Assignment Operators or update operators**

Augmented assignment statements

Augmented assignment is the combination, in a single statement, of a binary operation and an assignment statement

Operators Description and Example
-----------------------------------

a=a+2 → a+=2 b=5 b+=4*2  = A=5 A=A-1 → A-=1  *= A=5 A=A*2 → A*=2 B=3 A=A*B → A*=B  /= A=5 A=A/2 (OR) A/=2  //= A=5 A=A/2 (OR) A/=2  A=5 A+=5-=2 → Syntax Error  %= A=5 A=A%2 → A%=2  **= N1=4 N1=N1**2 → N1**=2  >>= A=5 A=A>>2 → A>>=2 <<= A=5 A=A<>2 → A<=2 A=5 A=A>>2 → A>>=2  <= A=5 A=A>>2 → A>=2  A=5 A=A>>2 → A>=2 A=5 A=A>>2 → A>=2 A=5 A=A>>2 → A>=2 A=5 A=A>>2 → A>=2 A=5 A=B=A=A>=A=A&B   = A=8 B=5 A =B → A=A B A=6	+=	a=5

Salary=5000 Salary=salary+200 → Salary+=200

Balance=90000
Balance=balance+10000 → balance+=10000

Balance-=5000 → balance=balance-5000

#### **Identity Operator**

Every object in python is having identity, which is called address In order to compare identity or address of objects we use identity operators.

- 1. is → return True, if two variable hold address of same object
- 2. is not → return True, if two variable hold different object addresses

```
>>> a=10
>>> b=10
>>> id(a)
92582472272
>>> id(b)
92582472272
>>> a==b
True
>>> a is b
True
>>> list1=[10,20,30,40,50]
>>> list2=[10,20,30,40,50]
>>> list1==list2
True
>>> list3=[30,20,10,40,50]
>>> list1==list3
False
>>> list1 is list2
False
>>> id(list1)
92596326208
>>> id(list2)
92626761152
>>> list4=list1
>>> list1 is list4
True
```

>>>

What difference is between == and is operator?

== operator is used to compare state of the object or values of the object Is operator is used to compare id of objects (OR) address of objects

```
>>> f1=1.5

>>> f2=1.5

>>> f1==f2

True

>>> id(f1)

92626355184

>>> id(f2)

92626354544

>>> f1 is f2

False

>>> f1 is not f2

True

>>>
```

#### **Membership operator**

Membership operators are used to search a given value exists within group values or collection of values

- 1. in
- 2. not in

Membership operator return Boolean value (True/False) It is a binary operator, it required 2 operands

- 1. value
- 2. collection

```
>>> 10 in [10,20,30,40,50]
True
>>> 60 in [10,20,30,40,50]
False
>>> "a" in "java"
True
>>> "python" in "python is language"
True
>>>
```

# **Example:**

# write a program to find input character is vowel or not ch=input("Enter any character") print("vowel") if ch in "aeiouAEIOU" else print("not vowel")

### Walrus operator

Walrus assignment operator := This operator is introduced in python 3.8 version

#### **Example:**

```
a=2
b=3
c=(x:=a**2)+(y:=b**2)+(z:=2*a*b)
print(a,b,c)
print(x,y,z)
Output:
2 3 25
4 9 12
>>>
```

## **Example:**

# write a program to add two numbers

```
n3=(n1:=int(input("Enter first number")))+(n2:=int(input("Enter second number")))
print(n1,n2,n3)
```

### **Output:**

Enter first number10 Enter second number20 10 20 30 >>>
